

# Battery State Estimation for a Single Particle Model With Electrolyte Dynamics

Scott J. Moura, *Member, IEEE*, Federico Bribiesca Argomodo, Reinhardt Klein, Anahita Mirtabatabaei, and Miroslav Krstic, *Fellow, IEEE*

**Abstract**—This paper studies a state estimation scheme for a reduced electrochemical battery model, using voltage and current measurements. Real-time electrochemical state information enables high-fidelity monitoring and high-performance operation in advanced battery management systems, for applications such as consumer electronics, electrified vehicles, and grid energy storage. This paper derives a single particle model (SPM) with electrolyte that achieves higher predictive accuracy than the SPM. Next, we propose an estimation scheme and prove estimation error system stability, assuming that the total amount of lithium in the cell is known. The state estimation scheme exploits the dynamical properties, such as marginal stability, local invertibility, and conservation of lithium. Simulations demonstrate the algorithm's performance and limitations.

**Index Terms**—Batteries, battery management systems, electrochemical devices, nonlinear dynamical systems, partial differential equations, stability analysis, state estimation.

## I. INTRODUCTION

THIS PAPER studies a state estimation algorithm based upon the single particle model with electrolyte (SPMe) dynamics—an electrochemical battery model. The algorithm features properties such as stability and conservation of lithium.

### A. Background and Motivation

Batteries are ubiquitous. They power a spectrum of devices, including consumer electronics, electrified vehicles, and smart grid systems. Control system technologies that enhance battery performance are of extreme interest. In particular, electrochemical model-based control systems provide visibility into operating regimes that induce degradation. This visibility enables a larger operational envelope to increase the

performance with respect to energy capacity, power capacity, and fast charge rates [1]. Electrochemical model-based state estimation is particularly challenging for several technical reasons. First, the dynamics are governed by a system of nonlinear partial differential algebraic equations [2], [3]. Second, local state observability does not hold globally [4]. Third, the model parameters vary widely with electrode chemistry, electrolyte, packaging, and time. Finally, the cells in battery packs are generally heterogeneous with respect to their parameters, temperature, and state of charge (SOC). This motivates an intimate understanding of the mathematical model structure for an observer design. In this paper, we address the first two technical challenges.

### B. Relevant Literature

Over the past decade, the engineering literature on battery estimation has grown considerably rich with various algorithms, models, and applications. One may categorize this literature by the battery models that each algorithm employs. Note that these studies inherently assume the pack or modules can be conceptualized as an aggregate single cell. This is valid when cell balancing, binning, and temperature management maintain homogeneity across the pack or module.

The first category utilizes equivalent circuit models (ECMs). These models use circuit elements to mimic the input–output behavior of batteries [5]. The seminal paper by Plett [6] was one of the first to apply extended Kalman filtering (EKF) to ECMs for simultaneous state and parameter estimation. Over the past decade, a variety of ECM-based algorithms have been developed, including linear parameter varying observers [7], sliding-mode observers [8], polynomial chaos [9], neural networks [10], unscented Kalman filters (KFs) [11], adaptive KFs [12], and particle filters [13].

The second category of the literature considers electrochemical models, which account for the diffusion, intercalation, and electrochemical kinetics. Although these models can accurately predict internal state variables, their mathematical structure renders observer design challenging. Consequently, most approaches develop estimators for the reduced-order models. The model reduction and the observer design process are intimately intertwined, as simpler models ease estimation design at the expense of fidelity. Ideally, one seeks to derive a provably stable estimator for the highest fidelity electrochemical battery model possible. The first wave of studies utilize the SPM for an estimator design [4], [14]–[17]. The SPM idealizes each electrode as a single spherical porous particle by neglecting the electrolyte dynamics. This model is suitable for low  $C$ -rates, but loses fidelity at  $C$ -rates above  $C/2$

(see Section II-C). Recently, there has been progress on extending the SPM to include electrolyte dynamics [18]–[22]. In several cases, state observers have been designed via linearization and Luenberger observers [23] or EKFs [24]. State estimation designs have also emerged for other electrochemical models that incorporate electrolyte dynamics. Examples include spectral methods with output error injection [25], residue grouping with Kalman filtering [26], semiseparable structures with an EKF [27], discrete-time realization algorithms with an EKF [28], and composite electrodes with nonlinear filters [29].

In all the aforementioned estimation studies for SPMe dynamics, a rigorous analysis of observer estimation error stability and conservation of lithium is lacking. In addition, all these methods are reliant on a particular numerical discretization scheme. That is, they discretize the partial differential equations (PDEs) immediately and, then, apply analysis and estimation synthesis in the finite-dimensional domain. This paper performs the analysis and estimation synthesis on the PDEs before discretization. The advantages are twofold: 1) one does not have to revisit the estimator design if the discretization method is altered and 2) the physical significance of the equations (and of the phenomena they represent) is retained regardless of the discretization method used at the implementation stage, thus yielding valuable insights as a by-product of the design process, which are lost in other approaches. Unfortunately, it becomes increasingly difficult to prove estimation error stability as model complexity increases, as highlighted in the referenced literature. The core difficulty is lack of complete observability from voltage measurements.

### C. Main Contributions

In this paper, we advance the aforementioned research by designing a PDE-based observer for an SPMe. The observer design is unique, since it exploits fundamental electrochemistry dynamic properties, yielding a deeper insight in battery state estimation. We additionally prove the stability of the estimation error system and conservation of lithium. Consequently, the article's main contributions are summarized as follows.

- 1) Derivation of an SPMe oriented toward the state estimation design. Similar models have been derived in [18]–[22]. We additionally analyze dynamical system properties that enable a provably convergent state estimator.
- 2) A PDE-based state estimation design that exploits marginal stability, conservation of lithium, and output function invertibility to render convergent estimates. We also include a rigorous stability analysis of the estimation error systems.

### D. Outline

The remainder of this paper is organized as follows. Section II derives the SPMe and analyzes relevant conservation properties, invertability, and accuracy relative to other electrochemical models. Section III derives the state estimation scheme for each constitutive subsystem. Section IV analyzes

Fig. 1. Schematic of the DFN model [2]. The model considers two phases: the solid and the electrolyte. In the solid, states evolve in the  $x$  and  $r$  dimensions. In the electrolyte, states evolve in the  $x$  dimension only. The cell is divided into three regions: anode, separator, and cathode.

the stability of the estimation error dynamics. The estimator is demonstrated via simulations in Section V. Finally, the conclusion is drawn in Section VI.

## II. SINGLE PARTICLE MODEL WITH ELECTROLYTE

### A. Doyle–Fuller–Newman Model

In this section, we describe the assumptions and steps followed to derive the SPMe model. First, we summarize the Doyle–Fuller–Newman (DFN) model in Fig. 1 to predict the evolution of lithium concentration in the solid  $c_s^\pm(x, r, t)$ , lithium concentration in the electrolyte  $c_e(x, t)$ , solid electric potential  $\phi_s^\pm(x, t)$ , electrolyte electric potential  $\phi_e(x, t)$ , ionic current  $i_e^\pm(x, t)$ , and molar ion fluxes  $j_n^\pm(x, t)$ . The governing equations are

$$\frac{\partial c_s^\pm}{\partial t}(x, r, t) = \frac{1}{r^2} \frac{\partial}{\partial r} \left[ D_s^\pm r^2 \frac{\partial c_s^\pm}{\partial r}(x, r, t) \right] \quad (1)$$

$$\varepsilon_e^j \frac{\partial c_e^j}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ D_e^{\text{eff}}(c_e^j) \frac{\partial c_e^j}{\partial x}(x, t) + \frac{1-t_c^0}{F} i_e^j(x, t) \right] \quad (2)$$

for  $j \in \{-, \text{sep}, +\}$  and

$$\sigma^{\text{eff}, \pm} \cdot \frac{\partial \phi_s^\pm}{\partial x}(x, t) = i_e^\pm(x, t) - I(t) \quad (3)$$

$$\kappa^{\text{eff}}(c_e) \cdot \frac{\partial \phi_e}{\partial x}(x, t) = -i_e^\pm(x, t) + \kappa^{\text{eff}}(c_e) \cdot \frac{2RT}{F} (1 - t_c^0) \times \left( 1 + \frac{d \ln f_{c/a}}{d \ln c_e}(x, t) \right) \frac{\partial \ln c_e}{\partial x}(x, t) \quad (4)$$

$$\frac{\partial i_e^\pm}{\partial x}(x, t) = a^\pm F j_n^\pm(x, t) \quad (5)$$

$$j_n^\pm(x, t) = \frac{1}{F} i_0^\pm(x, t) \left[ e^{\frac{a_a F}{RT} \eta^\pm(x, t)} - e^{-\frac{a_c F}{RT} \eta^\pm(x, t)} \right] \quad (6)$$

$$i_0^\pm(x, t) = k^\pm [c_{ss}^\pm(x, t)]^{a_c} \times [c_e(x, t) (c_{s, \max}^\pm - c_{ss}^\pm(x, t))]^{a_a} \quad (7)$$

$$\eta^\pm(x, t) = \phi_s^\pm(x, t) - \phi_e(x, t) - U^\pm(c_{ss}^\pm(x, t)) - F R_f^\pm j_n^\pm(x, t) \quad (8)$$

$$c_{ss}^\pm(x, t) = c_s^\pm(x, R_s^\pm, t) \quad (9)$$

where  $D_e^{\text{eff}} = D_e(c_e) \cdot (\varepsilon_e^j)^{\text{brugg}}$ ,  $\sigma^{\text{eff}} = \sigma \cdot (\varepsilon_s^j + \varepsilon_f^j)^{\text{brugg}}$ , and  $\kappa^{\text{eff}} = \kappa(c_e) \cdot (\varepsilon_e^j)^{\text{brugg}}$  are the effective electrolyte diffusivity, effective solid conductivity, and effective electrolyte conductivity given by the Bruggeman relationship.

The boundary conditions for solid-phase diffusion PDE (1) are

$$\frac{\partial c_s^\pm}{\partial r}(x, 0, t) = 0 \quad (10)$$

$$\frac{\partial c_s^\pm}{\partial r}(x, R_s^\pm, t) = -\frac{1}{D_s^\pm} j_n^\pm(x, t). \quad (11)$$

The boundary conditions for the electrolyte-phase diffusion PDE (2) are given by

$$\frac{\partial c_e^-}{\partial x}(0^-, t) = \frac{\partial c_e^+}{\partial x}(0^+, t) = 0 \quad (12)$$

$$D_e^{\text{eff}}(c_e(L^-)) \frac{\partial c_e^-}{\partial x}(L^-, t) = D_e^{\text{sep,eff}}(c_e(0^{\text{sep}})) \times \frac{\partial c_e^{\text{sep}}}{\partial x}(0^{\text{sep}}, t) \quad (13)$$

$$D_e^{\text{sep,eff}}(c_e(L^{\text{sep}})) \frac{\partial c_e^{\text{sep}}}{\partial x}(L^{\text{sep}}, t) = D_e^{+, \text{eff}}(c_e(L^+)) \frac{\partial c_e^+}{\partial x}(L^+, t) \quad (14)$$

$$c_e(L^-, t) = c_e(0^{\text{sep}}, t) \quad (15)$$

$$c_e(L^{\text{sep}}, t) = c_e(L^+, t). \quad (16)$$

The boundary conditions for the electrolyte-phase potential ordinary differential equation (ODE) (4) are given by

$$\phi_e(0^-, t) = 0 \quad (17)$$

$$\phi_e(L^-, t) = \phi_e(0^{\text{sep}}, t) \quad (18)$$

$$\phi_e(L^{\text{sep}}, t) = \phi_e(L^+, t). \quad (19)$$

The boundary conditions for the ionic current ODE (5) are given by

$$i_e^-(0^-, t) = i_e^+(0^+, t) = 0 \quad (20)$$

and also note that  $i_e(x, t) = I(t)$  for  $x \in [0^{\text{sep}}, L^{\text{sep}}]$ .

The model input is the applied current density  $I(t)$  [A/m<sup>2</sup>], and the output is the voltage measured across the current collectors

$$V(t) = \phi_s^+(0^+, t) - \phi_s^-(0^-, t). \quad (21)$$

A complete exposition on the model equations and notation can be found in [2] and [3]. Symbols are defined in Table III of the Appendix. Note the mathematical structure, which contains linear PDEs (1), quasi-linear PDEs (2), ODEs in space (3)–(5), and nonlinear algebraic constraints (6)–(8). This presents a formidable task for model-based state estimation. Consequently, we seek an appropriately reduced model that maintains prediction fidelity—at high  $C$ -rates in particular—yet enables a provably convergent state observer.

### B. SPMe Model Derivation

The SPMe is derived under the following assumptions.

[A1]: The solid-phase Li concentration in each electrode is constant in spatial coordinate  $x$ , uniformly in time. Mathematically,  $c_s^\pm(x, r, t)$  and  $j_n^\pm(x, t)$  are constant in the  $x$ -direction.

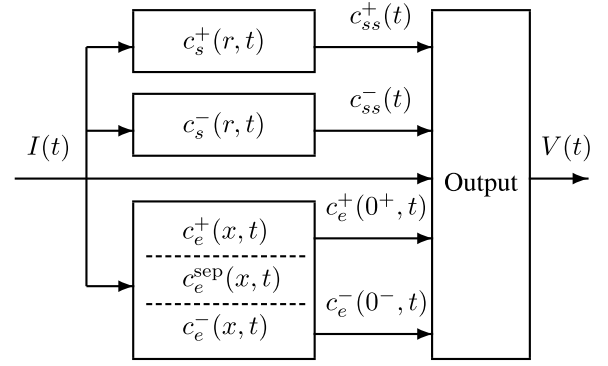

Fig. 2. Block diagram of SPMe. Note that the  $c_s^+$ ,  $c_s^-$ ,  $c_e$  subsystems are independent of one another.

Fig. 3. Simplified form of  $i_e(x, t)$  in the SPMe model.

[A2]: The exchange current density term  $i_0^\pm(x, t)$  can be approximated by its averaged value  $\bar{i}_0^\pm(t)$ , which is independent of  $x$ .

[A3]: The total moles of lithium in the electrolyte  $n_{\text{Li},e}$  and in the solid phase  $n_{\text{Li},s}$  are both conserved. This assumption, together with Assumption [A1], makes it possible to write the fluxes  $j_n^\pm(x, t)$  as proportional to current  $I(t)$ .

[A4]: The constants  $\alpha_a = \alpha_c$  (hereafter denoted simply by  $\alpha$ ). This assumption is almost always true in practice.

These assumptions ultimately render a model consisting of: 1) two linear spherical diffusion PDEs modeling each electrode's solid concentration dynamics; 2) a quasi-linear diffusion equation (across three domains) modeling the electrolyte concentration dynamics; and 3) a nonlinear output function mapping boundary values of solid concentration, electrolyte concentration, and current to voltage (see Fig. 2).

We now introduce the resulting SPMe equations. Whenever Assumptions [A1]–[A3] remove the spatial dependence of a variable, an overline is added to the variable name to avoid confusion. The first step is to combine Assumption [A1], ODE (5), and its boundary conditions (20) to express molar ion flux as proportional to current

$$\bar{j}_n^+(t) = -\frac{I(t)}{Fa^+L^+}, \quad \bar{j}_n^-(t) = \frac{I(t)}{Fa^-L^-}. \quad (22)$$

Note the ionic current  $i_e(x, t)$  has the trapezoidal shape shown in Fig. 3. Apply  $\bar{j}_n^\pm$  in (22) to boundary conditions (10) and (11) and Assumption [A1] to derive the solid diffusion equations

$$\frac{\partial \bar{c}_s^\pm}{\partial t}(r, t) = \frac{1}{r^2} \frac{\partial}{\partial r} \left[ D_s^\pm r^2 \frac{\partial \bar{c}_s^\pm}{\partial r}(r, t) \right] \quad (23)$$

$$\frac{\partial \bar{c}_s^\pm}{\partial r}(0, t) = 0, \quad \frac{\partial \bar{c}_s^\pm}{\partial r}(R_s^\pm, t) = \pm \frac{1}{D_s^\pm Fa^\pm L^\pm} I(t). \quad (24)$$

Next, derive the electrolyte diffusion equations by combining PDE (2) with (5), (22), and Assumption [A1]

$$\frac{\partial c_e^-}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}(c_e^-)}{\varepsilon_e^-} \frac{\partial c_e^-}{\partial x}(x, t) \right] + \frac{(1 - t_c^0)}{\varepsilon_e^- F L^-} I(t) \quad (25)$$

$$\frac{\partial c_e^{\text{sep}}}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}(c_e^{\text{sep}})}{\varepsilon_e^{\text{sep}}} \frac{\partial c_e^{\text{sep}}}{\partial x}(x, t) \right] \quad (26)$$

$$\frac{\partial c_e^+}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}(c_e^+)}{\varepsilon_e^+} \frac{\partial c_e^+}{\partial x}(x, t) \right] - \frac{(1 - t_c^0)}{\varepsilon_e^+ F L^+} I(t) \quad (27)$$

with the same boundary conditions as (12)–(16).

Next, we derive the nonlinear output function for terminal voltage. From (21), we note that the voltage  $V(t)$  depends on the solid potential at the current collectors  $\phi_s^\pm(x, t)$ . Therefore, we solve (8) in terms of  $\phi_s$  and spatially averaged quantities

$$\phi_s^\pm(x, t) = \bar{\eta}^\pm(t) + \bar{\phi}_e^\pm(x, t) + U^\pm(\bar{c}_{ss}^\pm(t)) + F R_f^\pm \bar{j}_n^\pm(t). \quad (28)$$

Next, we derive each term on the right-hand side of (28). Overpotential  $\bar{\eta}^\pm(t)$  is found by solving the Butler–Volmer equation (6) in terms of  $\bar{\eta}^\pm(t)$ , applying Assumptions [A1], [A2], and [A4], and substituting (22)

$$\bar{\eta}^\pm(t) = \frac{RT}{\alpha F} \sinh^{-1} \left( \frac{\mp I(t)}{2a^\pm L^\pm \bar{i}_0^\pm(t)} \right). \quad (29)$$

The electrolyte potential  $\bar{\phi}_e^\pm(x, t)$  is found by integrating ODE (4) with respect to  $x$  across the entire cell width

$$\begin{aligned} \int_{0^-}^{0^+} \frac{\partial \phi_e}{\partial x}(x, t) dx &= \int_{0^-}^{0^+} \frac{i_e^\pm(x, t)}{\kappa(c_e)} dx + \int_{0^-}^{0^+} \frac{2RT}{F} (1 - t_c^0) \\ &\quad \times \left( 1 + \frac{d \ln f_{c/a}}{d \ln c_e}(x, t) \right) \frac{\partial \ln c_e}{\partial x}(x, t) dx. \end{aligned} \quad (30)$$

In order to analytically integrate (30), we further assume the following.

[A5]: The term  $k_f(x, t) \doteq (1 + (d \ln f_{c/a}/d \ln c_e)(x, t))$  is approximately constant in  $x$ , i.e.,  $\bar{k}_f(t) \approx k_f(x, t)$ .

[A6]: The term  $\kappa(c_e)$  is approximately constant in  $c_e$ , i.e.,  $\bar{\kappa} \approx \kappa(c_e)$ .

This yields the expression

$$\begin{aligned} \bar{\phi}_e^+(0^+, t) - \bar{\phi}_e^-(0^-, t) &= \frac{L^+ + 2L^{\text{sep}} + L^-}{2\bar{\kappa}} I(t) \\ &\quad + \frac{2RT}{F} (1 - t_c^0) k_f(t) [\ln c_e(0^+, t) - \ln c_e(0^-, t)]. \end{aligned} \quad (31)$$

Now, we combine (22) and (28)–(31) to compute  $V(t) = \phi_s^+(0^+, t) - \phi_s^-(0^-, t)$

$$\begin{aligned} V(t) &= \frac{RT}{\alpha F} \sinh^{-1} \left( \frac{-I(t)}{2a^+ L^+ \bar{i}_0^+(t)} \right) \\ &\quad - \frac{RT}{\alpha F} \sinh^{-1} \left( \frac{I(t)}{2a^- L^- \bar{i}_0^-(t)} \right) \\ &\quad + U^+(\bar{c}_{ss}^+(t)) - U^-(\bar{c}_{ss}^-(t)) - \left( \frac{R_f^+}{a^+ L^+} + \frac{R_f^-}{a^- L^-} \right) I(t) \\ &\quad + \frac{L^+ + 2L^{\text{sep}} + L^-}{2\bar{\kappa}} I(t) \\ &\quad + k_{\text{conc}}(t) [\ln c_e(0^+, t) - \ln c_e(0^-, t)] \end{aligned} \quad (32)$$

$$V(t) = h(\bar{c}_{ss}^+, \bar{c}_{ss}^-, c_e^+(0^+, t), c_e^-(0^-, t), I(t)) \quad (33)$$

where  $k_{\text{conc}} = (2RT/F)(1 - t_c^0)k_f(t)$ .

This summarizes the SPMe. Note the significantly simplified structure. The dynamical equations (23) and (25)–(27) are linear and quasi-linear PDEs, respectively. The boundary conditions are all linear. Finally, the output function (32) is nonlinear with respect to states and inputs. As shown in Section III, the SPMe is amenable to state observer design with provable convergence. Moreover, it maintains accuracy at high  $C$ -rates, as discussed in Section II-C.

*Remark 1 (SPMe Versus SPM Comparison):* Note the voltage expression (32) is identical to the SPM voltage expression [15], but the SPMe adds the last two terms. These, respectively, represent ohmic potential drop due electrolyte conductivity and the electrolyte concentration overpotential.

*Remark 2 (Comparison With Existing SPMe Models):* The SPMe model development was motivated by the difficulty of extending the results in [15] using the models available in the literature. For instance, the model in [19] does not allow for the output-inversion step and we require to design a provably convergent observer, due to the spatial distribution of the surface concentration in the solid given by the interaction of the approximate diffusion representation and the polynomial (in space) approximation of the electrolyte concentration profiles.

The model in [21] linearizes the transportation equations first. Then, it applies a Laplace transformation and performs a polynomial approximation across space. This results in a linear output function, but produces a nonphysical state-space representation. The model we propose, in contrast, maintains the physical interpretation of the state space—a useful property for state estimation. Furthermore, our time-domain model can accommodate some time-varying coefficients in a much simpler way than an approximate transfer function model.

The models in [18], [20], and [22] are the most similar to the SPMe derived here, as they apply Assumption [A1] in addition to various numerical approximations. In [18], bulk solid concentration is used in the voltage output function instead of the surface concentration we use here (see [18, eq. (26)]). In the case of [20], volume averaging is performed in the electrolyte phase, which partially obscures electrolyte polarization. Han *et al.* [22] used an approximation of the solid state diffusion equation instead of retaining the PDE version we use in (23) and (24) (see [22, Sec. 2]). Since our main objective is provably convergent state observers, we additionally analyze the SPMe's dynamical properties in Section II-D. Furthermore, the structure of our proposed SPMe would allow for relatively simple extensions to nonhomogeneous (in space) transport and conductivity terms, albeit rendering the integration required to obtain the output equation in (32) harder. Namely, it would require numerically integrating the electrolyte potential gradient instead of obtaining an explicit form for the ohmic potential drop.

### C. Model Comparison

In this section, we compare the voltage predictions between the SPMe, SPM, and DFN models. Note the SPM output voltage equation is equivalent to (32), but without the last two terms. The model parameters used in this paper originate from the publicly available DUALFOIL simulation package [30]

Fig. 4. (a) Voltage discharge curves across various  $C$ -rates, for the SPM [15], SPMe, and DFN model [30]. The SPMe maintains smaller errors as  $C$ -rate increases relative to the SPM. (b) Electrolyte concentration  $c_e(x, t)$  predicted by DFN and SPMe for various  $C$ -rates after 5 Ah/m<sup>2</sup> of discharge. The concentration gradient increases as  $C$ -rate increases.

TABLE I  
RMS VOLTAGE ERROR WITH RESPECT TO DFN MODEL

|      | 0.1C | 0.5C | 1C    | 2C    | 5C    | UDDSx2 |
|------|------|------|-------|-------|-------|--------|
| SPM  | 2 mV | 8 mV | 17 mV | 31 mV | 72 mV | 14 mV  |
| SPMe | 2 mV | 5 mV | 9 mV  | 13 mV | 19 mV | 7 mV   |

and correspond to a lithium cobalt oxide cathode/graphite anode chemistry. Discharge curves at various  $C$ -rates are shown in Fig. 4(a). At low  $C$ -rates (e.g., 0.1C or 0.5C), the electrolyte concentration gradient is negligible and both the SPM and the SPMe accurately predict voltage. As  $C$ -rate increases beyond 0.5C, the electrolyte gradient becomes significant [see Fig. 4(b)], thereby violating the SPM model reduction assumption. Consequently, the SPMe predicts voltage with greater accuracy than the SPM (see Table I). Fig. 5 shows a visual comparison of the SPM, SPMe, and DFN models on a transient electric vehicle-like charge/discharge cycle, generated from two concatenated Urban Dynamometer Driving Schedules (UDDSx2) (see [31] for details). The mean  $C$ -rate is about 0.5C. The SPM predicts voltage with 14 mV rms error, whereas the SPMe achieves 7-mV rms error. Clearly,

Fig. 5. Comparison of SPM, SPMe, and DFN model predictions on two concatenated UDDS charge/discharge cycles.

battery management systems for the applications with large sustained  $C$ -rates greatly benefit from models with electrolyte dynamics. This, however, complicates an observer design—a challenge we address in this paper.

#### D. Mathematical Model Properties

The causal structure of the SPMe is shown in Fig. 2. Namely, the  $c_s^+$ ,  $c_s^-$ , and  $c_e$  subsystems are mutually independent of one another. Moreover, they are governed by linear ( $c_s^+$  subsystem) or quasi-linear ( $c_e$  subsystems) PDEs. Note the bar notation used in Section II-B is herein after dropped to reduce clutter. Note also that the PDE subsystems produce the boundary values  $c_{ss}^+(t)$ ,  $c_{ss}^-(t)$ ,  $c_e^+(0^+, t)$ , and  $c_e^-(0^-, t)$  that serve as inputs to the nonlinear output function. We pursue the following observer structure, which exploits the linear PDE dynamical subsystems and nonlinear output function: 1) design linear observers for each dynamical subsystem, assuming a virtual measurement of  $c_{ss}^+(t)$  and 2) design a recursive nonlinear output function inversion scheme to process  $c_{ss}^+(t)$  from measurements  $I(t)$  and  $V(t)$ .

The model is also characterized by the following dynamical properties, which are the critical insights underpinning the observer design in Section III. We present Propositions 1–3, whose proofs are straightforward, noninsightful within themselves, and omitted for brevity.

**Proposition 1 (Marginal Stability of  $c_s^+$ ,  $c_s^-$ , and  $c_e$  Subsystems):** Each individual subsystem in (23)–(27) governing states  $c_s^+(r, t)$ ,  $c_s^-(r, t)$ , and  $c_e(x, t)$  is marginally stable. In particular, each subsystem contains one eigenvalue at the origin, and the remaining eigenvalues lie on the negative real axis of the complex plane.

**Proposition 2 (Conservation of Solid-Phase Lithium):** The moles of lithium in the solid phase are conserved [25].

Mathematically,  $(d/dt)(n_{\text{Li},s}(t)) = 0$ , where

$$n_{\text{Li},s}(t) = \sum_{j \in \{+, -\}} \frac{\varepsilon_s^j L^j}{\frac{4}{3}\pi (R_s^j)^3} \int_0^{R_s^j} 4\pi r^2 c_s^j(r, t) dr. \quad (34)$$

In the following observer design, we select the estimation gains to conserve moles of lithium.

*Proposition 3 (Conservation of Electrolyte-Phase Lithium):*

The moles of lithium in the electrolyte phase are conserved. Mathematically,  $(d/dt)(n_{\text{Li},e}(t)) = 0$ , where

$$n_{\text{Li},e}(t) = \sum_{j \in \{-, \text{sep}, +\}} \varepsilon_e^j \int_{0^j}^{L^j} c_e^j(x, t) dx. \quad (35)$$

In particular, this property implies that the equilibrium solution of the  $c_e$  subsystem (25)–(27) with zero current density, i.e.,  $I(t) = 0$ , is given by

$$c_{e,\text{eq}}(x) = \frac{n_{\text{Li},e}}{\varepsilon_e^- L^- + \varepsilon_e^{\text{sep}} L^{\text{sep}} + \varepsilon_e^+ L^+} \quad \forall x \in [0^-, 0^+]. \quad (36)$$

### E. Invertibility Analysis

Next, we study the invertibility of the output function (32) with respect to boundary state variables  $c_{ss}^\pm(t)$ . Invertibility enables one to process surface concentration from measurements  $I(t)$  and  $V(t)$  and design linear observers. Let output function  $h : \mathbb{R} \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$  be defined, such that  $V(t) = h(c_{ss}^+, c_{ss}^-, I)$ , where we assume that the electrolyte concentrations  $c_e^\pm(0^\pm, t)$  in (33) are known and, therefore, suppress their dependence. This assumption is valid, because we later substitute exponentially convergent estimates of  $c_e^\pm(0^\pm, t)$  into output function  $h(\cdot)$ , as shown in Section IV. The output function  $h(c_{ss}^+, c_{ss}^-, \cdot)$  is locally invertible around  $c_s^\pm = a$  or  $c_s^\pm = b$ , if  $h(c_{ss}^+, c_{ss}^-, \cdot)$  is one-to-one in the respective local domains  $\{c_{ss}^+ : |c_{ss}^+ - a| < \epsilon\}$  or  $\{c_{ss}^- : |c_{ss}^- - b| < \epsilon\}$ , for small  $\epsilon > 0$ . If the aforementioned condition is true for all  $I$ , then  $h(a, b, \cdot)$  is locally invertible uniformly in  $I$ . Consequently, invertibility can be tested by examining the gradient of  $h(c_{ss}^+, c_{ss}^-, \cdot)$  with respect to  $c_{ss}^+$  or  $c_{ss}^-$ .

Under equilibrium conditions and zero current, the output function simplifies to

$$V(t) = U^+(c_{ss}^+(t)) - U^-(c_{ss}^-(t)). \quad (37)$$

Fig. 6(a) shows the open-circuit potential (OCP) functions  $U^-(\theta^-)$  and  $U^+(\theta^+)$ , where  $\theta^\pm = c_{ss}^\pm / c_{s,\text{max}}^\pm$ . In general,  $U^+(\theta^+)$  is more sensitive to perturbations in its argument than  $U^-(\theta^-)$ . Fig. 6(b) shows the partial derivatives of  $h(c_{ss}^+, c_{ss}^-, I)$  in (33) with respect to  $c_{ss}^-$  and  $c_{ss}^+$  at equilibrium conditions, for currents ranging from  $-5C$  to  $+5C$ . In general,  $h$  is nondecreasing with respect to  $c_{ss}^-$  and is nonincreasing with respect to  $c_{ss}^+$ . It is important to note that  $h$  is strictly monotonically decreasing with respect to  $c_{ss}^+$  over a larger range than  $h$  is strictly monotonically increasing with respect to  $c_{ss}^-$ . This property is critical, since it demonstrates that voltage is generally more sensitive to perturbations in cathode surface concentration than anode surface concentration. Consequently, we opt to pursue output function inversion with respect to  $c_{ss}^+$  instead of  $c_{ss}^-$ . Note  $\partial h / \partial c_{ss}^+ \approx 0$  for  $0.8 \leq \theta^+ \leq 0.9$ . This region is a blind spot with respect to output inversion, a

Fig. 6. (a) OCP functions  $U^-(\theta^-)$ ,  $U^+(\theta^+)$  and (b) gradients of  $h(c_{ss}^+, c_{ss}^-, I)$  in (33), as the functions of normalized surface concentration  $\theta^\pm = c_{ss}^\pm / c_{s,\text{max}}^\pm$ , for currents ranging from  $-5C$  to  $+5C$ .

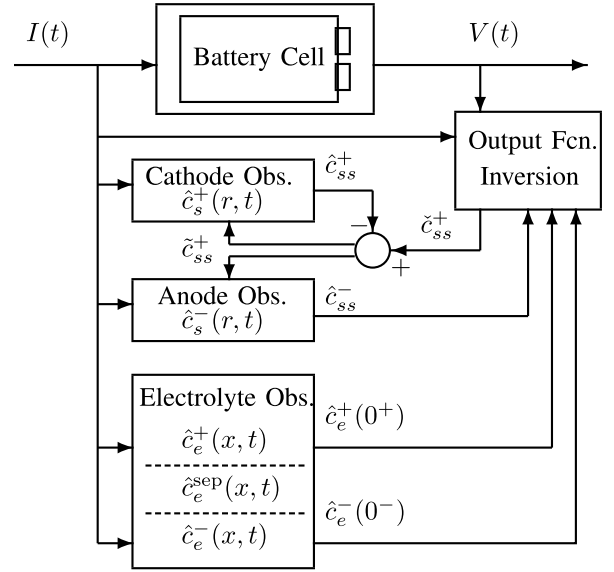

Fig. 7. Block diagram of SPMe observer.

limitation we explore by the analysis in Section IV-B and by the simulation in Section V.

### III. STATE OBSERVER DESIGN

Fig. 7 provides a block diagram of the SPMe observer. The observer design process is summarized as follows.

- 1) Perform dimension normalization and state transformation on cathode dynamics.
- 2) Design a backstepping PDE observer for the transformed cathode dynamics.
- 3) Perform inverse state transformation and unnormalization.
- 4) Design anode observer to conserve lithium in solid.
- 5) Design an open-loop electrolyte observer.
- 6) Design an output function inversion scheme.

### A. Normalization and State Transformation

First, we perform normalization and state transformation to simplify the mathematical structure of the cathode observer. The radial  $r$  and time  $t$  coordinates are scaled as follows:

$$\bar{r} = \frac{r}{R_s^+}, \quad \bar{t} = \frac{D_s^+}{(R_s^+)^2} t. \quad (38)$$

Henceforth, we will drop the bars over the space and time coordinates to simplify notation. Next, we perform a state transformation to eliminate the first spatial derivative in the spherical diffusion equation (23). Namely, let

$$c(r, t) = r c_s^+(r, t). \quad (39)$$

This normalization and state transformation produces the following PDE with Dirichlet and Robin boundary conditions:

$$\frac{\partial c}{\partial t}(r, t) = \frac{\partial^2 c}{\partial r^2}(r, t) \quad (40)$$

$$c(0, t) = 0 \quad (41)$$

$$\frac{\partial c}{\partial r}(1, t) - c(1, t) = \rho I(t). \quad (42)$$

The parameter  $\rho = R_s^+ / (D_s^+ F a^+ L^+)$  groups together known parameters.

### B. Cathode Backstepping Observer

The cathode state estimator subsystem structure consists of a copy of the plant (40)–(42) plus boundary state error injection as follows:

$$\frac{\partial \hat{c}}{\partial t}(r, t) = \frac{\partial^2 \hat{c}}{\partial r^2}(r, t) + p^+(r)[c(1, t) - \hat{c}(1, t)] \quad (43)$$

$$\hat{c}(0, t) = 0 \quad (44)$$

$$\frac{\partial \hat{c}}{\partial r}(1, t) - \hat{c}(1, t) = \rho I(t) + p_0^+[c(1, t) - \hat{c}(1, t)]. \quad (45)$$

Following the procedure in [15] and [32], the observer gains are:

$$p^+(r) = \frac{-\lambda r}{2z} \left[ I_1(z) - \frac{2\lambda}{z} I_2(z) \right] \quad (46)$$

where

$$z = \sqrt{\lambda(r^2 - 1)} \quad (47)$$

$$p_0^+ = \frac{1}{2}(3 - \lambda), \quad \text{for } \lambda < \frac{1}{4} \quad (48)$$

and  $I_1(z)$  and  $I_2(z)$  are, respectively, the first- and second-order modified Bessel functions of the first kind. Parameter  $\lambda$  governs the error system eigenvalue locations.

### C. Inverse Transformation and Unnormalization

Next, we rewrite the cathode observer (43)–(45) into the original coordinates  $\hat{c}_s^+$  by inverting transformation (39) and unnormalizing the dimensions (38). The final result is

$$\frac{\partial \hat{c}_s^+}{\partial t}(r, t) = D_s^+ \left[ \frac{2}{r} \frac{\partial \hat{c}_s^+}{\partial r}(r, t) + \frac{\partial^2 \hat{c}_s^+}{\partial r^2}(r, t) \right] + \bar{p}^+(r)[c_{ss}^+(t) - \hat{c}_{ss}^+(t)] \quad (49)$$

$$\frac{\partial \hat{c}_s^+}{\partial r}(0, t) = 0 \quad (50)$$

$$\frac{\partial \hat{c}_s^+}{\partial r}(R_s^+, t) = \frac{I(t)}{D_s^+ F a^+ L^+} + \bar{p}_0^+[c_{ss}^+(t) - \hat{c}_{ss}^+(t)]. \quad (51)$$

where the observer gains are

$$\bar{p}^+(r) = \frac{-\lambda D_s^+}{2R_s^+ \bar{z}} \left[ I_1(\bar{z}) - \frac{2\lambda}{\bar{z}} I_2(\bar{z}) \right] \quad (52)$$

where

$$\bar{z} = \sqrt{\lambda \left( \frac{r^2}{(R_s^+)^2} - 1 \right)} \quad (53)$$

$$\bar{p}_0^+ = \frac{1}{2R_s^+}(3 - \lambda), \quad \text{for } \lambda < \frac{1}{4}. \quad (54)$$

### D. Anode Observer

Now, we focus on an observer for the anode subsystem. Our objective is to design the observer gains, such that the total moles of solid-phase lithium are conserved. The anode state estimator subsystem structure consists of a copy of the plant (23) plus cathode surface concentration error injection as follows:

$$\frac{\partial \hat{c}_s^-}{\partial t}(r, t) = D_s^- \left[ \frac{2}{r} \frac{\partial \hat{c}_s^-}{\partial r}(r, t) + \frac{\partial^2 \hat{c}_s^-}{\partial r^2}(r, t) \right] + \bar{p}^-(r)[c_{ss}^+(t) - \hat{c}_{ss}^+(t)] \quad (55)$$

$$\frac{\partial \hat{c}_s^-}{\partial r}(0, t) = 0 \quad (56)$$

$$\frac{\partial \hat{c}_s^-}{\partial r}(R_s^-, t) = \frac{I(t)}{D_s^- F a^- L^-} + \bar{p}_0^- [c_{ss}^+(t) - \hat{c}_{ss}^+(t)]. \quad (57)$$

We seek to design  $\bar{p}^-(r)$ ,  $\bar{p}_0^-$ , such that  $(d/dt)(\hat{n}_{Li,s}(t)) = 0$ . This property holds true under the following relations between the estimation gains:

$$a^+ L^+ D_s^+ \bar{p}_0^+ + a^- L^- D_s^- \bar{p}_0^- = 0 \quad (58)$$

$$\frac{a^+ L^+}{(R_s^+)^2} \int_0^{R_s^+} r^2 \bar{p}^+(r) dr + \frac{a^- L^-}{(R_s^-)^2} \int_0^{R_s^-} r^2 \bar{p}^-(r) dr = 0. \quad (59)$$

Imposing the structure  $\bar{p}^-(r) = \bar{p}^-$  for  $r \in [0, R_s^+]$ , we obtain the anode gains in terms of the cathode gains

$$\bar{p}_0^- = -\frac{a^+ L^+ D_s^+}{a^- L^- D_s^-} \bar{p}_0^+ \quad (60)$$

$$\bar{p}^- = -\frac{a^+ L^+}{(R_s^+)^2 \varepsilon_s^- L^-} \int_0^{R_s^+} r^2 \bar{p}^+(r) dr \quad (61)$$

where  $\varepsilon_s^- = 3/(a^- R_s^-)$ .

### E. Solid-Phase Initial Estimate

The observer is initialized according to the assumption.

[A7]: The total moles of lithium in the solid phase,  $n_{Li,s}$  in (34), are known beforehand.

Therefore, the initial conditions for the composite observer (55)–(57) and (49)–(51) must verify

$$n_{Li,s} = \sum_{j \in \{+, -\}} \frac{\varepsilon_s^j L^j}{\frac{4}{3} \pi (R_s^j)^3} \int_0^{R_s^j} 4\pi r^2 \hat{c}_s^j(r, 0) dr \quad (62)$$

which has the physical interpretation that the observer and the plant have identical total moles of lithium in the solid,

uniformly in time. If we further consider initial estimates corresponding to a steady-state condition, i.e., the concentrations are uniform in  $r$ , then (62) simplifies to

$$n_{\text{Li},s} = \varepsilon_s^+ L^+ \hat{c}_{s,0}^+ + \varepsilon_s^- L^- \hat{c}_{s,0}^- \quad (63)$$

where  $\hat{c}_{s,0}^+$  and  $\hat{c}_{s,0}^-$  are the initial estimates corresponding to the steady state. In practice, the value of  $n_{\text{Li},s}$  might be provided by the cell maker, or identified via offline model parameterization schemes [33], [34], or online capacity estimators [15], [35]. We examine relaxing Assumption [A7] in Section V-C.

#### F. Electrolyte Observer

For the electrolyte subsystems, we apply an open-loop observer of the form

$$\frac{\partial \hat{c}_e^-}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}}{\varepsilon_e^-} \frac{\partial \hat{c}_e^-}{\partial x}(x, t) \right] + \frac{1 - t_c^0}{\varepsilon_e^- F L^-} I(t) \quad (64)$$

$$\frac{\partial \hat{c}_e^{\text{sep}}}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}}{\varepsilon_e^{\text{sep}}} \frac{\partial \hat{c}_e^{\text{sep}}}{\partial x}(x, t) \right] \quad (65)$$

$$\frac{\partial \hat{c}_e^+}{\partial t}(x, t) = \frac{\partial}{\partial x} \left[ \frac{D_e^{\text{eff}}}{\varepsilon_e^+} \frac{\partial \hat{c}_e^+}{\partial x}(x, t) \right] - \frac{1 - t_c^0}{\varepsilon_e^+ F L^+} I(t) \quad (66)$$

with boundary conditions

$$\frac{\partial \hat{c}_e^-}{\partial x}(0^-, t) = \frac{\partial \hat{c}_e^+}{\partial x}(0^+, t) = 0 \quad (67)$$

$$D_e^{\text{eff}}(c_e(L^-)) \frac{\partial \hat{c}_e^-}{\partial x}(L^-, t) = D_e^{\text{sep,eff}}(c_e(0^{\text{sep}})) \times \frac{\partial \hat{c}_e^{\text{sep}}}{\partial x}(0^{\text{sep}}, t) \quad (68)$$

$$D_e^{\text{sep,eff}}(c_e(L^{\text{sep}})) \frac{\partial \hat{c}_e^{\text{sep}}}{\partial x}(L^{\text{sep}}, t) = D_e^{+, \text{eff}}(c_e(L^+)) \times \frac{\partial \hat{c}_e^+}{\partial x}(L^+, t) \quad (69)$$

$$\hat{c}_e^-(L^-, t) = \hat{c}_e^{\text{sep}}(0^{\text{sep}}, t) \quad (70)$$

$$\hat{c}_e^{\text{sep}}(L^{\text{sep}}, t) = \hat{c}_e^+(L^+, t). \quad (71)$$

The observer is initialized according to the following assumption.

[A8]: The total moles of lithium in the electrolyte,  $n_{\text{Li},e}$  in (35), are known beforehand.

Therefore, the initial conditions for the electrolyte observer (64)–(71) must verify

$$n_{\text{Li},e} = \sum_{j \in \{-, \text{sep}, +\}} \varepsilon_e^j \int_{0^j}^{L^j} \hat{c}_e^j(x, 0) dx \quad (72)$$

which has the physical interpretation that the observer and plant have identical total moles of lithium in the electrolyte, uniformly in time. If we further consider initial estimates corresponding to a steady-state condition, i.e., the concentrations are uniform in  $x$ , then (72) simplifies to

$$\hat{c}_e^j(x, 0) = \frac{n_{\text{Li},e}}{\varepsilon_e^- L^- + \varepsilon_e^{\text{sep}} L^{\text{sep}} + \varepsilon_e^+ L^+}, \quad j \in \{-, \text{sep}, +\}. \quad (73)$$

In practice, the value of  $n_{\text{Li},e}$  might be provided by the cell maker, or identified via offline model parameterization schemes [33], [34]. We examine relaxing Assumption [A8] in Section V-D.

TABLE II  
SUMMARY OF SPM<sub>e</sub> OBSERVER EQUATIONS

| Subsystem             | State Vars.  | Diff. Eqns.          | Design Params.         |
|-----------------------|--|----------------------|------------------------|
| Cathode, solid phase  | $\hat{c}_{ss}^+(r, t)$   | (49)–(54)            | $\lambda$ in (52)–(54) |
| Anode, solid phase    | $\hat{c}_{ss}^-(r, t)$   | (55)–(57), (60)–(61) |                        |
| Electrolyte           | $\hat{c}_e^-(x, t)$<br>$\hat{c}_e^{\text{sep}}(x, t)$<br>$\hat{c}_e^+(x, t)$ | (64)–(71)            | none                   |
| Output Fcn. Inversion | $\check{c}_{ss}^+(t)$  | (77)–(78)            | $\gamma$ in (78)       |

#### G. Output Function Inversion

In Sections III-A–III-D, we designed the linear state observers assuming access to surface concentration (i.e., boundary value)  $c_{ss}^+(t)$ . In this section, we develop a nonlinear gradient algorithm to compute  $c_{ss}^+(t)$  from measurements  $I(t)$  and  $V(t)$  by inverting the nonlinear output function (32).

To focus on the task at hand, we rewrite the output function as

$$V(t) = h(c_{ss}^+, t) \quad (74)$$

where the dependence on  $c_{ss}^-(t)$ ,  $c_e^-(0^-, t)$ , and  $c_e^+(0^+, t)$  has been suppressed into a singular dependence on  $t$ . Denote  $\check{c}_{ss}^+(t)$  as the processed cathode surface concentration resulting from this output function inversion procedure. Then, the error between the true and processed values is  $\tilde{\theta} = c_{ss}^+ - \check{c}_{ss}^+$ . Now, rewrite (74) as

$$V(t) = h(\tilde{\theta} + \check{c}_{ss}^+, t). \quad (75)$$

Next, we approximate the right-hand side of (75) using the first-order Taylor series with respect to  $\tilde{\theta}$  about  $\tilde{\theta} = 0$

$$V(t) \approx h(\check{c}_{ss}^+, t) + \frac{\partial h}{\partial c_{ss}^+}(\check{c}_{ss}^+, t) \cdot \tilde{\theta}. \quad (76)$$

Define inversion error and regressor signals  $e_{nl}(t)$  and  $\phi(t)$ , respectively, as

$$e_{nl}(t) = V(t) - h(\check{c}_{ss}^+, t), \quad \phi(t) = \frac{\partial h}{\partial c_{ss}^+}(\check{c}_{ss}^+, t). \quad (77)$$

The approximated output function can now be written in the regressor form as  $e_{nl}(t) = \phi(t)\tilde{\theta}$ . A gradient update law for  $\check{c}_{ss}^+(t)$  that minimizes  $(1/2)\gamma e_{nl}^2(t)$  is given by [36]

$$\frac{d}{dt} \check{c}_{ss}^+(t) = \gamma \phi e_{nl}. \quad (78)$$

Note that gain  $\gamma$  is a user-selected parameter to trade off convergence speed and sensitivity to noise.

*Remark 3:* The update law (78) can be embellished in two practically useful ways. First, a nonlinear least squares update can be applied to dynamically determine the gain parameter (see [36, Sec. 4.3]). Second, the projection operator can be applied to constrain  $\check{c}_{ss}^+(t)$  within the set  $[c_{s,\min}^+, c_{s,\max}^+]$  (see [36, Sec. 4.4]).

#### H. Summary of Observer Design

The complete SPM<sub>e</sub> observer design is summarized in Table II. It summarizes each subsystem with a reference to the appropriate differential equations. Note the observer has only two scalar design parameters,  $\lambda$  and  $\gamma$ . Parameter

$\lambda$  governs the eigenvalues of the cathode observer subsystem, and  $\gamma$  governs the output inversion convergence speed. KF-based observers, in contrast, typically have much more than two parameters, depending on the discretization method. In particular, KFs have up to  $(n_x^2 + n_x)/2 + (n_y^2 + n_y)/2$  tuning parameters, where  $n_x$  and  $n_y$  are the number of states and measurements, respectively. The small number of tuning parameters is an additional benefit of the proposed observer design, in addition to provable stability properties.

#### IV. STABILITY ANALYSIS

In this section, we prove the stability of the composite observer, comprised of the solid-phase and electrolyte-phase subsystems, assuming the measurements of cathode surface concentration  $c_{ss}^+(t)$ . We also prove the convergence of the output inversion scheme under an appropriate monotonicity assumption.

##### A. Solid + Electrolyte Phase Estimation Error Stability

Consider the cathode ( $\tilde{c}_s^+$ ) and anode ( $\tilde{c}_s^-$ ) estimation error subsystems, where  $\tilde{c}_s^+ = c_s^+ - \hat{c}_s^+$  and  $\tilde{c}_s^- = c_s^- - \hat{c}_s^-$

$$\frac{\partial \tilde{c}_s^+}{\partial t}(r, t) = D_s^+ \left[ \frac{2}{r} \frac{\partial \tilde{c}_s^+}{\partial r}(r, t) + \frac{\partial^2 \tilde{c}_s^+}{\partial r^2}(r, t) \right] - \bar{p}^+(r) \tilde{c}_{ss}^+(t) \quad (79)$$

$$\frac{\partial \tilde{c}_s^+}{\partial r}(0, t) = 0, \quad \frac{\partial \tilde{c}_s^+}{\partial r}(R_s^+, t) = -\bar{p}_0^+ \tilde{c}_{ss}^+(t) \quad (80)$$

$$\tilde{c}_{ss}^+(r, 0) = c_{ss}^+(r, 0) - \hat{c}_{ss}^+(r, 0) \quad (81)$$

$$\frac{\partial \tilde{c}_s^-}{\partial t}(r, t) = D_s^- \left[ \frac{2}{r} \frac{\partial \tilde{c}_s^-}{\partial r}(r, t) + \frac{\partial^2 \tilde{c}_s^-}{\partial r^2}(r, t) \right] - \bar{p}^-(r) \tilde{c}_{ss}^-(t) \quad (82)$$

$$\frac{\partial \tilde{c}_s^-}{\partial r}(0, t) = 0, \quad \frac{\partial \tilde{c}_s^-}{\partial r}(R_s^-, t) = -\bar{p}_0^- \tilde{c}_{ss}^-(t) \quad (83)$$

$$\tilde{c}_{ss}^-(r, 0) = c_{ss}^-(r, 0) - \hat{c}_{ss}^-(r, 0). \quad (84)$$

To derive the electrolyte estimation error system,  $\tilde{c}_e^j = c_e^j - \hat{c}_e^j$ ,  $j \in \{-, \text{sep}, +\}$ , we assume the following assumption.

[A9]: The electrolyte diffusivity is approximately constant in  $c_e$ , i.e.,  $\bar{D}_e^{\text{eff}} \approx D_e^{\text{eff}}(c_e)$ .

Under Assumption [A9], the electrolyte estimation error subsystem is

$$\frac{\partial \tilde{c}_e^-}{\partial t}(x, t) = \frac{\bar{D}_e^{\text{eff}}}{\varepsilon_e^-} \frac{\partial^2 \tilde{c}_e^-}{\partial x^2}(x, t) \quad (85)$$

$$\frac{\partial \tilde{c}_e^{\text{sep}}}{\partial t}(x, t) = \frac{\bar{D}_e^{\text{eff}}}{\varepsilon_e^{\text{sep}}} \frac{\partial^2 \tilde{c}_e^{\text{sep}}}{\partial x^2}(x, t) \quad (86)$$

$$\frac{\partial \tilde{c}_e^+}{\partial t}(x, t) = \frac{\bar{D}_e^{\text{eff}}}{\varepsilon_e^+} \frac{\partial^2 \tilde{c}_e^+}{\partial x^2}(x, t) \quad (87)$$

with boundary conditions

$$\frac{\partial \tilde{c}_e^-}{\partial x}(0^-, t) = \frac{\partial \tilde{c}_e^+}{\partial x}(0^+, t) = 0 \quad (88)$$

$$\bar{D}_e^{\text{eff},-} \frac{\partial \tilde{c}_e^-}{\partial x}(L^-, t) = \bar{D}_e^{\text{eff},\text{sep}} \frac{\partial \tilde{c}_e^{\text{sep}}}{\partial x}(0^{\text{sep}}, t) \quad (89)$$

$$\bar{D}_e^{\text{eff},\text{sep}} \frac{\partial \tilde{c}_e^{\text{sep}}}{\partial x}(L^{\text{sep}}, t) = \bar{D}_e^{\text{eff},+} \frac{\partial \tilde{c}_e^+}{\partial x}(L^+, t) \quad (90)$$

$$\tilde{c}_e^-(L^-, t) = \tilde{c}_e^{\text{sep}}(0^{\text{sep}}, t) \quad (91)$$

$$\tilde{c}_e^{\text{sep}}(L^{\text{sep}}, t) = \tilde{c}_e^+(L^+, t) \quad (92)$$

and initial condition

$$\tilde{c}_e^j(x, 0) = c_e^j(x, 0) - \hat{c}_e^j(x, 0), \quad j \in \{-, \text{sep}, +\}. \quad (93)$$

We are now positioned to state the stability of the combined estimation error systems.

*Theorem 1:* Consider the combined estimation error dynamics (79)–(93) for  $\tilde{c}_s^+(r, t)$ ,  $\tilde{c}_s^-(r, t)$ , and  $\tilde{c}_e^j(x, t)$ .

- 1) The solid-phase estimation error subsystem (79)–(84) converges asymptotically to the zero equilibrium if  $\tilde{c}_s^\pm(r, 0)$  verifies (63). That is,  $\lim_{t \rightarrow \infty} \tilde{c}_s^+(r, t) = \lim_{t \rightarrow \infty} \tilde{c}_s^-(r, t) = 0$ , uniformly in  $r$ .
- 2) The electrolyte-phase estimation error system (85)–(93) converges asymptotically to the zero equilibrium if  $\tilde{c}_e^j(x, 0)$  verifies (73).

*Proof:* The solid-phase error subsystem  $\tilde{c}_s^\pm$  and the electrolyte-phase error subsystem  $\tilde{c}_e^j$  are decoupled. Therefore, we can prove statements 1 and 2 separately.

1) *Solid-Phase Error System:* Note the error subsystems form a Cascade. Upstream subsystem  $\tilde{c}_s^+$  is autonomous and downstream subsystem  $\tilde{c}_s^-$  evolves with  $\tilde{c}_{ss}^+(t)$  as an input. The upstream subsystem  $\tilde{c}_s^+$  is exponentially stable by the construction of the backstepping observer [32, Th. 2]. Consequently, we focus on the stability of downstream subsystem  $\tilde{c}_s^-$  with zero input, i.e.,  $\tilde{c}_{ss}^+(t) = 0$

$$\frac{\partial \tilde{c}_s^-}{\partial t}(r, t) = D_s^- \left[ \frac{2}{r} \frac{\partial \tilde{c}_s^-}{\partial r}(r, t) + \frac{\partial^2 \tilde{c}_s^-}{\partial r^2}(r, t) \right] \quad (94)$$

$$\frac{\partial \tilde{c}_s^-}{\partial r}(0, t) = \frac{\partial \tilde{c}_s^-}{\partial r}(R_s^-, t) = 0. \quad (95)$$

It is straightforward to show this system has infinite equilibria, since it contains one eigenvalue at the origin and the remaining eigenvalues exist on the negative real axis. Consequently, the anode error dynamics are marginally stable.

Not coincidentally, the structure and the initialization of the observer ensure that the anode error system converges asymptotically to the zero equilibrium. Consider the error between the total moles of lithium in the plant and observer

$$n_{\text{Li},s}(t) - \hat{n}_{\text{Li},s}(t) = n_{\text{Li},s} - n_{\text{Li},s} = 0 \quad \forall t \in \mathbb{R}^+ \quad (96)$$

by assumption Assumption [A7], Proposition 2, and construction of the estimator initial condition. Rewriting (96) in terms of the error states

$$0 = \sum_{j \in \{+, -\}} \frac{\varepsilon_s^j L^j}{\frac{4}{3} \pi (R_s^j)^3} \int_0^{R_s^j} 4 \pi r^2 \tilde{c}_s^j(r, t) dr \quad \forall t \in \mathbb{R}^+. \quad (97)$$

Consider the limit as time approaches infinity

$$0 = \lim_{t \rightarrow \infty} \left\{ \sum_{j \in \{+, -\}} \frac{\varepsilon_s^j L^j}{\frac{4}{3} \pi (R_s^j)^3} \int_0^{R_s^j} 4 \pi r^2 \tilde{c}_s^j(r, t) dr \right\}$$

$$0 = \sum_{j \in \{+, -\}} \frac{\varepsilon_s^j L^j}{\frac{4}{3} \pi (R_s^j)^3} \int_0^{R_s^j} 4 \pi r^2 \cdot \lim_{t \rightarrow \infty} \tilde{c}_s^j(r, t) dr. \quad (98)$$

Now, apply the following two properties.

- 1)  $\lim_{t \rightarrow \infty} \tilde{c}_s^+(r, t) = 0$  uniformly in  $r$ , due to the exponential stability of (79) and (80) [32].
- 2) The equilibrium structure of (94) and (95) implies that  $\lim_{t \rightarrow \infty} \tilde{c}_s^-(r, t) = \tilde{c}_{s,\text{eq}}^-$  is uniform in  $r \in [0, R_s^-]$ .

Then, (98) reduces to

$$0 = \frac{\varepsilon_s^- L^-}{\frac{4}{3}\pi (R_s^-)^3} \int_0^{R_s^-} 4\pi r^2 \cdot \tilde{c}_{s,\text{eq}}^- dr \quad (99)$$

$$0 = \varepsilon_s^- L^- \cdot \tilde{c}_{s,\text{eq}}^- \quad (100)$$

$$0 = \tilde{c}_{s,\text{eq}}^- \quad (101)$$

Therefore, the subsystem (94) and (95) converges asymptotically to the zero equilibrium, that is,  $\lim_{t \rightarrow \infty} \tilde{c}_s^-(r, t) = 0 \forall r \in [0, R_s^-]$ . Since the error subsystems form a Cascade, the composite error system is asymptotically stable.

2) *Electrolyte-Phase Error System*: The proof of statement 2 consists of three main steps. First, apply coordinate scaling and composition to transform (85)–(93) into a heat equation with homogeneous Neumann boundary conditions. Second, compute the solution using the separation of variables. Third, show the solution converges asymptotically to the zero equilibrium if (73) is verified.

*Step 1*: For notational simplicity, denote  $\delta_1 = \varepsilon_e^- \bar{D}_e$ ,  $\delta_2 = \varepsilon_e^{\text{sep}} \bar{D}_e$ , and  $\delta_3 = \varepsilon_e^+ \bar{D}_e$ . Next, decompose and transform the  $x$ -coordinate as follows:

$$\begin{aligned} \xi_1 &= \frac{x}{\delta_1}, \quad \xi_2 = \frac{x}{\delta_2} + \left( \frac{L^-}{\delta_1} - \frac{L^-}{\delta_2} \right) \\ \xi_3 &= \frac{x}{\delta_3} + \left( \frac{L^{\text{sep}} - L^-}{\delta_2} + \frac{L^-}{\delta_1} - \frac{L^{\text{sep}}}{\delta_3} \right). \end{aligned} \quad (102)$$

which yields

$$\frac{\partial \tilde{c}_e^-}{\partial t}(\xi_1, t) = \frac{\bar{D}_e}{\delta_1^2} \frac{\partial^2 \tilde{c}_e^-}{\partial \xi_1^2}(\xi_1, t) \quad (103)$$

$$\frac{\partial \tilde{c}_e^{\text{sep}}}{\partial t}(\xi_2, t) = \frac{\bar{D}_e}{\delta_2^2} \frac{\partial^2 \tilde{c}_e^{\text{sep}}}{\partial \xi_2^2}(\xi_2, t) \quad (104)$$

$$\frac{\partial \tilde{c}_e^+}{\partial t}(\xi_3, t) = \frac{\bar{D}_e}{\delta_3^2} \frac{\partial^2 \tilde{c}_e^+}{\partial \xi_3^2}(\xi_3, t) \quad (105)$$

with boundary conditions

$$\frac{\partial \tilde{c}_e^-}{\partial \xi_1}(l_{01}, t) = \frac{\partial \tilde{c}_e^+}{\partial \xi_3}(l_{30}, t) = 0 \quad (106)$$

$$\frac{\partial \tilde{c}_e^-}{\partial \xi_1}(l_{12}, t) = \frac{\partial \tilde{c}_e^{\text{sep}}}{\partial \xi_2}(l_{12}, t) \quad (107)$$

$$\frac{\partial \tilde{c}_e^{\text{sep}}}{\partial \xi_2}(l_{23}, t) = \frac{\partial \tilde{c}_e^+}{\partial \xi_3}(l_{23}, t) \quad (108)$$

$$\tilde{c}_e^-(l_{12}, t) = \tilde{c}_e^{\text{sep}}(l_{12}, t) \quad (109)$$

$$\tilde{c}_e^{\text{sep}}(l_{23}, t) = \tilde{c}_e^+(l_{23}, t) \quad (110)$$

where

$$\begin{aligned} l_{01} &= \frac{0^-}{\delta_1}, \quad l_{12} = \frac{L^-}{\delta_1}, \quad l_{23} = \frac{L^-}{\delta_1} + \frac{L^{\text{sep}} - L^-}{\delta_2} \\ l_{30} &= \frac{L^-}{\delta_1} + \frac{L^{\text{sep}} - L^-}{\delta_2} + \frac{0^+ - L^{\text{sep}}}{\delta_3}. \end{aligned} \quad (111)$$

We now concatenate the spatial coordinate, state, and diffusion coefficient into single variables

$$\xi = \begin{cases} \xi_1, & \text{if } l_{01} \leq \xi \leq l_{12} \\ \xi_2, & \text{if } l_{12} < \xi < l_{23} \\ \xi_3, & \text{if } l_{23} \leq \xi \leq l_{30} \end{cases} \quad (112)$$

$$w(\xi, t) = \begin{cases} \tilde{c}_e^-(\xi, t), & \text{if } l_{01} \leq \xi \leq l_{12} \\ \tilde{c}_e^{\text{sep}}(\xi, t), & \text{if } l_{12} < \xi < l_{23} \\ \tilde{c}_e^+(\xi, t), & \text{if } l_{23} \leq \xi \leq l_{30} \end{cases} \quad (113)$$

$$\bar{D}(\xi) = \begin{cases} \frac{\bar{D}_e}{\delta_1^2}, & \text{if } l_{01} \leq \xi \leq l_{12} \\ \frac{\bar{D}_e}{\delta_2^2}, & \text{if } l_{12} < \xi < l_{23} \\ \frac{\bar{D}_e}{\delta_3^2}, & \text{if } l_{23} \leq \xi \leq l_{30}. \end{cases} \quad (114)$$

By continuity of  $\xi$  and  $\tilde{c}_e^j(\xi, t)$  across the three regions in (103)–(110), we can rewrite the system into a simple heat equation with homogeneous Neumann boundary conditions

$$\frac{\partial w}{\partial t}(\xi, t) = \bar{D}(\xi) \frac{\partial^2 w}{\partial \xi^2}(\xi, t) \quad (115)$$

$$\frac{\partial w}{\partial \xi}(l_{01}, t) = \frac{\partial w}{\partial \xi}(l_{30}, t) = 0 \quad (116)$$

$$w(\xi, 0) = c_e(\xi, 0) - \hat{c}_e(\xi, 0). \quad (117)$$

Next, we normalize the spatial variable  $\zeta = (\xi - l_{01})/(l_{30} - l_{01})$  to obtain

$$\frac{\partial w}{\partial t}(\zeta, t) = \bar{\bar{D}}(\zeta) \frac{\partial^2 w}{\partial \zeta^2}(\zeta, t) \quad (118)$$

$$\frac{\partial w}{\partial \zeta}(0, t) = \frac{\partial w}{\partial \zeta}(1, t) = 0 \quad (119)$$

$$w(\zeta, 0) = c_e(\zeta, 0) - \hat{c}_e(\zeta, 0). \quad (120)$$

where  $\bar{\bar{D}}(\zeta) = (1/(l_{30} - l_{01})^2) \bar{D}((l_{30} - l_{01})\zeta + l_{01})$ . The final step is to apply a gauge transformation [37] to obtain a heat equation with a spatially invariant diffusion coefficient

$$z = \sqrt{D_0} \int_0^\zeta \frac{ds}{\sqrt{\bar{\bar{D}}(s)}}, \quad \text{where } D_0 = \left( \int_0^1 \frac{ds}{\sqrt{\bar{\bar{D}}(s)}} \right)^{-2}. \quad (121)$$

This yields the heat equation

$$\frac{\partial w}{\partial t}(z, t) = D_0 \frac{\partial^2 w}{\partial z^2}(z, t) \quad (122)$$

$$\frac{\partial w}{\partial z}(0, t) = \frac{\partial w}{\partial z}(1, t) = 0 \quad (123)$$

$$w(z, 0) = c_e(z, 0) - \hat{c}_e(z, 0). \quad (124)$$

*Step 2*: Next, we solve (122)–(124) using the separation of variables. Let us consider the solution form

$$w(z, t) = Z(z) \cdot T(t). \quad (125)$$

Following the procedure in many PDE textbooks [37], [38], we obtain the solution:

$$w(z, t) = A_0 + \sum_{n=1}^{\infty} A_n \cos(n\pi z) \cdot e^{-D_0 n^2 \pi^2 t} \quad (126)$$

where the Fourier sine series coefficients are

$$A_0 = \int_0^1 w(z, 0) dz, \quad (127)$$

$$A_n = 2 \int_0^1 w(z, 0) \cos(n\pi z) dz, \quad n = 1, 2, 3, \dots \quad (128)$$

Note the second term on the right-hand side of (126) decays to zero exponentially fast in time. Therefore, we focus on showing  $A_0 = 0$ .

*Step 3:* Next, we show  $A_0 = 0$  in (127). To prove this, we perform the reverse coordinate transformation procedure from Step 1, namely,  $z \mapsto \zeta \mapsto \xi \mapsto (\xi_1, \xi_2, \xi_3) \mapsto x$ . This ultimately results in

$$A_0 = \int_0^1 w(z, 0) dz = \sqrt{D_0 \bar{D}_e} \sum_{j \in \{-, \text{sep}, +\}} \varepsilon_e^j \int_0^L \tilde{c}_e^j(x, 0) dx. \quad (129)$$

Using the definition of  $n_{\text{Li},e}$  in (35) and applying initial condition constraint (73) yield

$$A_0 = \int_0^1 w(z, 0) dz = \sqrt{D_0 \bar{D}_e} (n_{\text{Li},e} - n_{\text{Li},e}) = 0. \quad (130)$$

As a result,  $w(z, t)$  converges asymptotically (exponentially, in fact) to zero. Since all transformations are invertible, (79)–(83) converge asymptotically to the zero equilibrium. ■

*Remark 4:* The solution for  $w(x, t)$  in (126) exposes the dynamical structure for the electrolyte's estimation error dynamics. Namely, the solution is characterized by a constant  $A_0$  determined by the error in the initial estimation of the total amount of lithium in the electrolyte, plus exponentially decaying terms with eigenvalues  $\lambda_n = -D_0 \cdot n^2 \pi^2$  on the negative real axis of the complex plane, which increase quadratically toward  $-\infty$  as  $n$  increases.

### B. Output Function Inversion Convergence

In the following analysis, we prove the convergence of the output inversion scheme over a compact set of surface concentration, which satisfies the following assumption.

[A10]: The output function (74) has negative and bounded gradient

$$-M_2 \leq \frac{\partial h}{\partial c_{ss}^+}(c_{ss}^+, t) \leq -M_1 < 0 \quad \forall c_{ss}^+ \in \mathcal{D}, t \in \mathbb{R}^+ \quad (131)$$

where  $0 < M_1 < M_2$ . For example, we can pick  $\mathcal{D} = [0.1c_{s,\max}^+, 0.8c_{s,\max}^+]$  from Fig. 6.

*Theorem 2:* Let the error between the true and processed values be  $\tilde{\theta} = c_{ss}^+ - \check{c}_{ss}^+$ . Furthermore, assume the dynamics of  $\check{c}_{ss}^+$  are significantly faster than  $c_{ss}^+$ . Then,  $\tilde{\theta}(t)$  evolves according to the error system

$$\frac{d}{dt} \tilde{\theta}(t) = -\gamma \phi e_{nl} \quad (132)$$

where

$$\gamma > 0, \quad \phi = \frac{\partial h}{\partial c_{ss}^+}(\check{c}_{ss}^+, t), \quad e_{nl} = h(c_{ss}^+, t) - h(\check{c}_{ss}^+, t). \quad (133)$$

Under Assumption [A10],  $\tilde{\theta}$  converges exponentially to the zero equilibrium on the compact set  $c_{ss}^+, \check{c}_{ss}^+ \in \mathcal{D}$ . More specifically, for all initial conditions  $c_{ss}^+(0), \check{c}_{ss}^+(0) \in \mathcal{D}$ , the following holds:

$$|\tilde{\theta}(0)|^2 \cdot e^{-2\gamma \cdot M_2^2 \cdot t} \leq |\tilde{\theta}(t)|^2 \leq |\tilde{\theta}(0)|^2 \cdot e^{-2\gamma \cdot M_1^2 \cdot t} \quad \forall t \in \mathbb{R}^+. \quad (134)$$

*Proof:* The proof uses the mean value theorem approach for systems with monotone nonlinearities [39], [40]. Consider

$$e_{nl} = h(c_{ss}^+, t) - h(\check{c}_{ss}^+, t) = \chi(1) - \chi(0) \quad (135)$$

where we define  $\chi(\alpha) = h(\check{c}_{ss}^+ + \alpha \tilde{\theta}, t)$ . The total derivative of  $\chi(\alpha)$  is

$$\frac{d\chi}{d\alpha}(\alpha) = \frac{\partial h}{\partial c_{ss}^+} \frac{dc_{ss}^+}{d\alpha} = \frac{\partial h}{\partial c_{ss}^+} \tilde{\theta}. \quad (136)$$

Now, we invoke the fundamental theorem of calculus

$$e_{nl} = \chi(1) - \chi(0) = \int_0^1 \frac{d\chi}{d\alpha}(\alpha) d\alpha = \int_0^1 \frac{\partial h}{\partial c_{ss}^+} \cdot \tilde{\theta} \cdot d\alpha. \quad (137)$$

We are now positioned to propose the Lyapunov function

$$W(t) = \frac{1}{2\gamma} \tilde{\theta}^2(t). \quad (138)$$

The derivative of  $W(t)$  along the trajectories of  $\tilde{\theta}$  is given by

$$\begin{aligned} \frac{d}{dt} W(t) &= \frac{1}{\gamma} \tilde{\theta}(t) \dot{\tilde{\theta}}(t) = -\tilde{\theta} \cdot \phi \cdot e_{nl} \\ &= -\tilde{\theta} \cdot \frac{\partial h}{\partial c_{ss}^+} \cdot \int_0^1 \frac{\partial h}{\partial c_{ss}^+} \cdot \tilde{\theta} \cdot d\alpha \end{aligned} \quad (139)$$

where we have used (132), (133), and (137). Applying (131) from Assumption [A10] yields

$$\begin{aligned} -M_2^2 \cdot \tilde{\theta}^2(t) &\leq \frac{d}{dt} W(t) \leq -M_1^2 \cdot \tilde{\theta}^2(t) \\ -M_2^2 \cdot 2\gamma \cdot W(t) &\leq \frac{d}{dt} W(t) \leq -M_1^2 \cdot 2\gamma \cdot W(t). \end{aligned} \quad (140)$$

Therefore, we conclude the zero equilibrium of (132) is exponentially stable [41]. Applying the comparison principle yields

$$W(0) \cdot e^{-2\gamma \cdot M_2^2 \cdot t} \leq W(t) \leq W(0) \cdot e^{-2\gamma \cdot M_1^2 \cdot t} \quad \forall t \in \mathbb{R}^+. \quad (141)$$

Using the definition of  $W(t)$  in (138) yields

$$|\tilde{\theta}(0)|^2 \cdot e^{-2\gamma \cdot M_2^2 \cdot t} \leq |\tilde{\theta}(t)|^2 \leq |\tilde{\theta}(0)|^2 \cdot e^{-2\gamma \cdot M_1^2 \cdot t} \quad \forall t \in \mathbb{R}^+. \quad (142)$$

*Remark 5 (Output Inversion Limitation):* The significance of Assumption [A10] and Theorem 2 is that convergence is guaranteed only when  $h(c_{ss}^+, t)$  is strictly decreasing with respect to  $c_{ss}^+$ . If the gradient  $\partial h / \partial c_{ss}^+$  is zero, then convergence is not guaranteed, a property we explore by the simulation in Section V-A.

*Remark 6 (Stability Analysis for Fully Composed Observer):* The preceding sections analyze the convergence of the individual observer systems (solid + electrolyte phase, output inversion), assuming perfect knowledge of the corresponding inputs. Analyzing stability of the fully composed observer is very complex, given the interconnected structure of the observer subsystems. In particular, the solid-phase observer and the output inversion are interconnected, whereas the electrolyte observer is autonomous. Instead, we pursue simulations next to obtain empirical insight into the fully composed observer's convergence properties.

## V. SIMULATIONS

This section presents the simulations that demonstrate the SPMe observer's performance. Ideally, we prefer experimentally measured electrochemical state data to validate the proposed observer. Unfortunately, *in situ* measurements of lithium concentrations are very difficult. The few successful efforts use neutron imaging on custom-made and test-specific cells, such as [42]–[44]. In this paper, we apply the observer to the DFN model (1)–(21). The model parameters used in this paper originate from the publicly available DUALFOIL simulation package [30] and correspond to a LiCoO<sub>2</sub> cathode/graphite anode chemistry. The DFN model's numerical implementation is summarized in [1, Sec. II-C].

For all presented simulations, the state estimates are initialized at incorrect values. Namely, the true initial condition is  $c_s^-(r, 0)/c_{s,\max}^- = 0.8224$  and the observer's initial condition is  $\hat{c}_s^-(r, 0)/c_{s,\max}^- = 0.4$ . The following important parameters are also assumed:  $n_{\text{Li},s} = 2.5$  moles,  $n_{\text{Li},e} = 0.085$  moles,  $\lambda = -0.5$ , and  $\gamma = 10^8$ , unless otherwise specified. Surface concentrations are given by  $\theta^\pm = c_{ss}^\pm/c_{s,\max}^\pm$ .

Ultimately, the PDE-based observer must be discretized into ODEs for simulation. Although numerical schemes are not the focus of this paper (see [45], [46], and references therein), we summarize the methods applied here. The solid-phase and electrolyte observers are discretized in space via the central finite difference method, with the second-order one-sided finite differences at all boundary conditions [47]. A crucial step in the numerical integration scheme is to supply analytic Jacobians, which accelerates convergence and increases accuracy [1].

### A. Constant 1C Discharge Cycle

First, we consider a constant 1C discharge cycle in Fig. 8. Sustained C-rates are challenging, since they induce nonnegligible electrolyte gradients. Despite incorrect initial conditions and model mismatch (SPMe observer versus DFN truth model), the processed cathode surface concentration  $\hat{\theta}^+(t)$  converges to the true value, followed by convergent estimates of surface concentrations  $\hat{\theta}^-(t)$ ,  $\hat{\theta}^+(t)$ . After the initial transient ( $\sim 750$  sec), the estimates have the rms errors of 2.39%, 1.46%, and 8.6 mV for the anode surface concentration, cathode surface concentration, and voltage, respectively. Note that the estimates temporarily diverge in the range  $0.8 < \theta^+ < 0.9$ . In this range, the output function's derivative with respect to  $c_{ss}^+$  is nearly zero (see Fig. 6), meaning that the output function is nearly noninvertible. This feature is a fundamental limitation of battery state estimation, as discussed previously in the literature [29] and exposed in Theorem 2. The estimates recover as  $\theta^+$  enters a more strongly invertible range. Note the SPMe observer resolves the constant high C-rate deficiencies of the previous SPM-based observers [15, Sec. 7.2].

### B. Electric Vehicle Charge/Discharge Cycle

Second, we apply an electric vehicle charge/discharge cycle in Fig. 9. This input signal in Fig. 9(a) is generated from two concatenated UDDS drive cycles simulated on models developed in [31]. Unlike the previous input, this cycle is

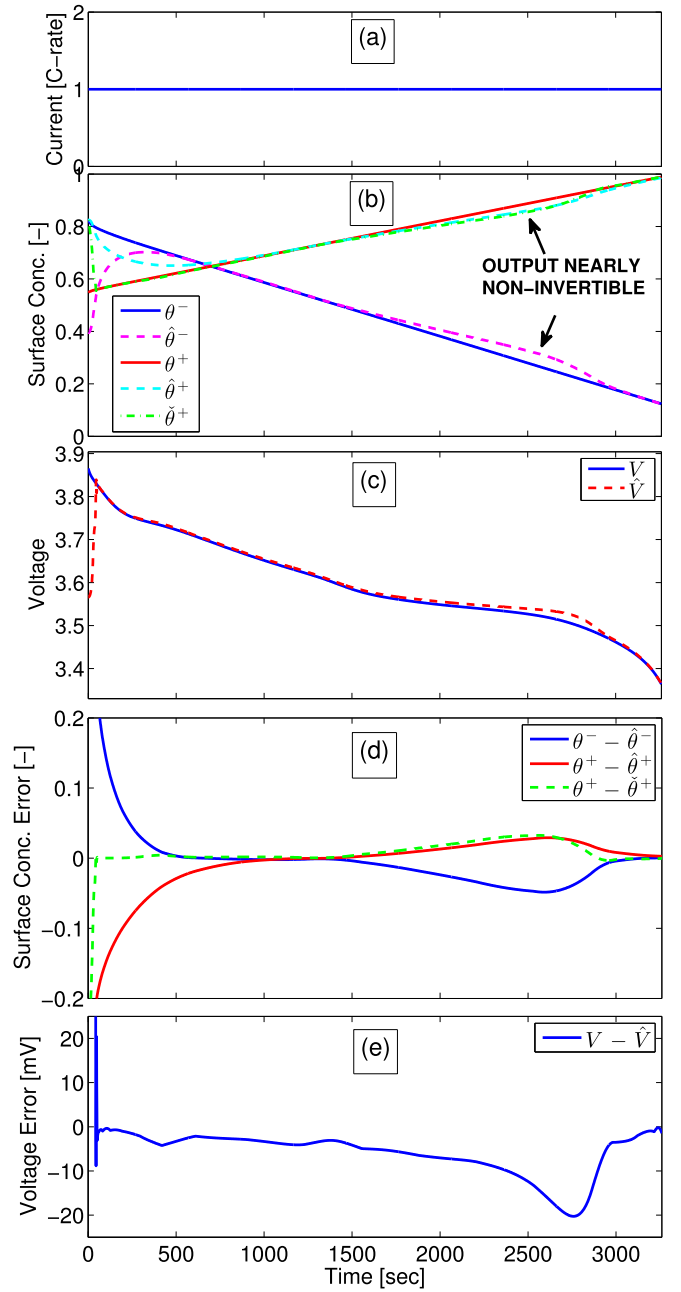

Fig. 8. SPMe observer results for a 1C constant current discharge, using DFN as truth model. True initial condition:  $c_s^-(r, 0)/c_{s,\max}^- = 0.8224$ . Observer initial condition:  $\hat{c}_s^-(r, 0)/c_{s,\max}^- = 0.4$ . (a) Input current. (b) Surface concentrations  $\theta^\pm = c_{ss}^\pm/c_{s,\max}^\pm$ . (c) Voltage. (d) Surface concentration estimation error. (e) Voltage estimation error.

characterized by larger nonsustained C-rates. The mean square C-rate is 1.28C and the absolute maximum C-rate is 5.43C. After the initial transient ( $\sim 750$  s), the estimates have the rms errors of 0.60%, 0.30%, and 6.7 mV for the anode surface concentration, cathode surface concentration, and voltage, respectively [see Fig. 9(d) and (e)]. Note the SPMe observer estimates output voltage with significantly higher accuracy than the previous SPM-based observers [15, Sec. 7.1]. Similar estimation results occur for various other initial conditions and drive cycle inputs, including US06, SC04, LA92, and naturalistic microtrip data.

Fig. 9. SPMe observer results for a UDDSx2 charge/discharge cycle, using DFN as the truth model. True initial condition:  $c_s^-(r, 0)/c_{s,\max}^- = 0.8224$ . Observer initial condition:  $\hat{c}_s^-(r, 0)/c_{s,\max}^- = 0.4$ . (a) Input current. (b) Surface concentrations  $\theta^\pm = c_{ss}^\pm/c_{s,\max}^\pm$ . (c) Voltage. (d) Surface concentration estimation error. (e) Voltage estimation error.

### C. Error in Moles of Solid Lithium $n_{Li,s}$

Third, we examine robustness with respect to error in the perceived moles of solid lithium, i.e.,  $\hat{n}_{Li,s}$ . Recall from Section III-E that a correct value of  $n_{Li,s}$  is required for stability Assumption [A7]. We now relax this assumption. This elucidates the impact of capacity fade on the observer performance. Again, we apply the UDDS charge/discharge cycle in Fig. 9(a), but intentionally supply the observer with 5% more lithium than the truth model, i.e.,  $\hat{n}_{Li,s} = 1.05 \times n_{Li,s} = 2.625$  moles. The simulation shown in Fig. 10 demonstrates an estimation bias resulting from an inaccurate total amount of solid lithium. After the initial transient ( $\sim 750$  s), the rms

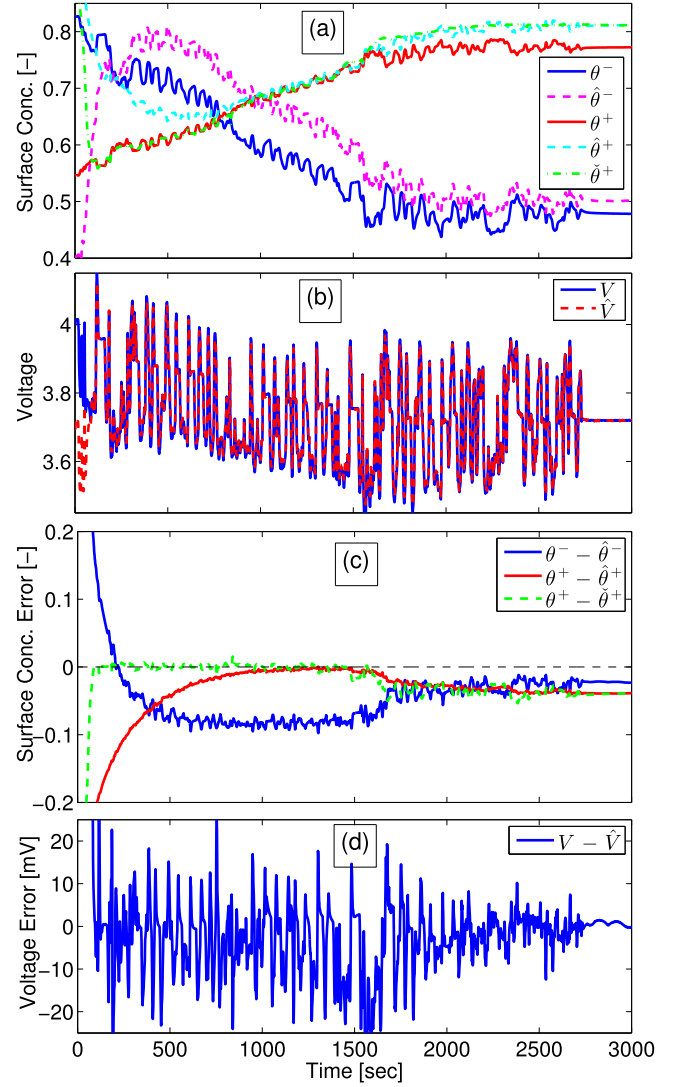

Fig. 10. SPMe observer results for a UDDSx2 charge/discharge cycle, using DFN as the truth model and incorrect  $n_{Li,s}$  value. True initial condition:  $c_s^-(r, 0)/c_{s,\max}^- = 0.8224$ . Observer initial condition:  $\hat{n}_{Li,s} = 1.05 \times n_{Li,s}$ ,  $\hat{c}_s^-(r, 0)/c_{s,\max}^- = 0.4$ . (a) Surface concentrations  $\theta^\pm = c_{ss}^\pm/c_{s,\max}^\pm$ . (b) Voltage. (c) Surface concentration estimation error. (d) Voltage estimation error.

estimation errors are 5.20% and 2.87% for the anode and cathode surface concentrations, respectively. This is roughly a ten times error increase relative to the case with a correct  $n_{Li,s}$  value. Importantly, note the voltage estimation error (7.4-mV rms) is nearly the same as with a correct value of  $n_{Li,s}$ , despite biased concentration estimates. This occurs because the observer converges on overestimated surface concentrations that satisfy  $\hat{n}_{Li,s} = 1.05 \times n_{Li,s}$  and produce a solid potential difference that yields the same value as the true concentrations. Therefore, the SPMe observer achieves estimated output convergence, yet produces biased solid concentration state estimates. This motivates: 1) accurate knowledge of  $n_{Li,s}$  for a fresh cell and 2) a real-time parameter estimation algorithm to determine how  $n_{Li,s}$  evolves as the battery ages [15].

### D. Error in Moles of Electrolyte Lithium $n_{Li,e}$

Finally, we examine robustness with respect to error in the perceived moles of electrolyte lithium, i.e.,  $\hat{n}_{Li,e}$ . Recall

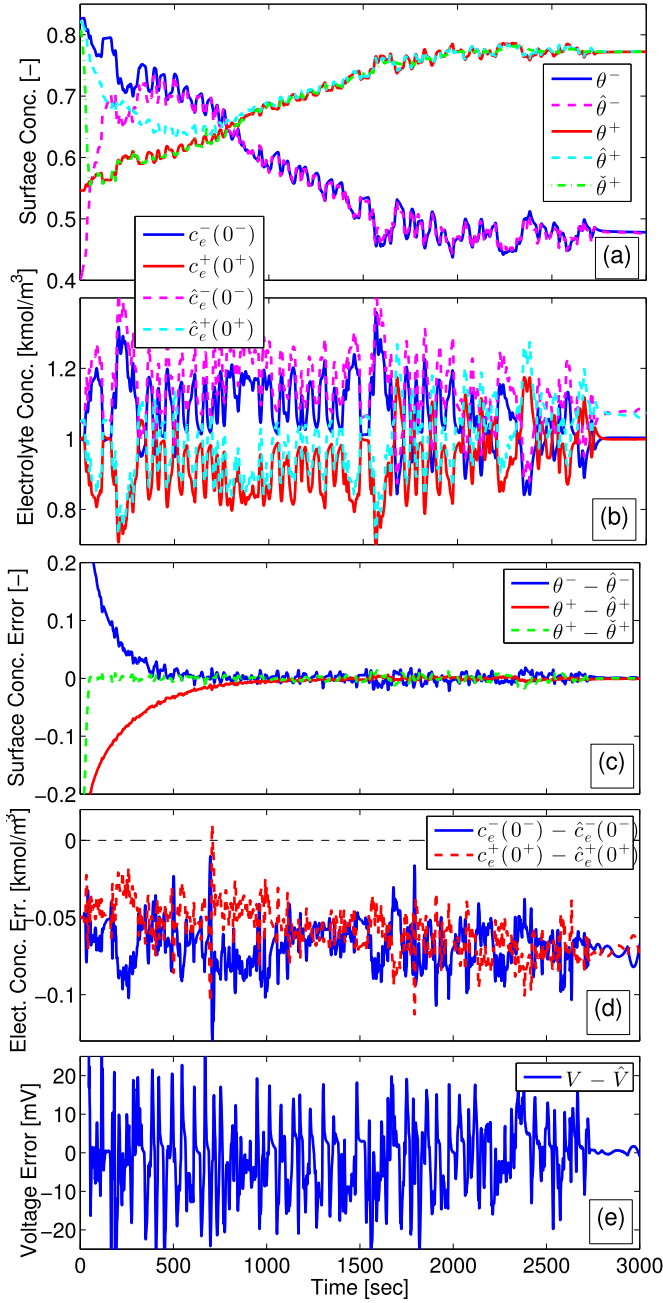

Fig. 11. SPMe observer results for a UDDSx2 charge/discharge cycle, using DFN as the truth model and incorrect  $n_{Li,e}$  value. True initial condition:  $c_s^-(r, 0)/c_{s,max}^- = 0.8224$ . Observer initial condition:  $\hat{n}_{Li,e} = 1.05 \times n_{Li,e}$ ,  $\hat{c}_s^-(r, 0)/c_{s,max}^- = 0.4$ . (a) Surface concentrations  $\theta^\pm = c_{ss}^\pm/c_{s,max}^\pm$ . (b) Voltage. (c) Surface concentration estimation error. (d) Voltage estimation error.

from Section III-F that a correct value of  $n_{Li,e}$  is required for stability Assumption [A8]. We now investigate the impact of relaxing this assumption. Again, we apply the UDDS charge/discharge cycle in Fig. 9(a), but intentionally supply the observer with 5% more lithium than the truth model, i.e.,  $\hat{n}_{Li,e} = 1.05 \times n_{Li,e} = 0.0893$  moles. Interestingly, the simulation shown in Fig. 11(a) and (c) demonstrates no estimation bias for the surface concentrations. Namely, the rms estimation errors after the initial transient ( $\sim 750$  s) are 0.58% and 0.33% for the anode and cathode surface concentrations, respectively. This is similar to the results with a correct value

TABLE III  
NOMENCLATURE

Symbols in order of appearance

| Electrochemical model states, inputs, outputs |  |
|---|--|
| $c_s^\pm$                                     | Lithium concentration in solid phase [mol/m <sup>3</sup> ]                           |
| $c_e$   | Lithium concentration in electrolyte phase [mol/m <sup>3</sup> ]                     |
| $\phi_s^\pm$                                  | Solid electric potential [V]   |
| $\phi_e$                                      | Electrolyte electric potential [V]   |
| $i_e^\pm$                                     | Ionic current [A/m <sup>2</sup> ]  |
| $j_a^\pm$                                     | Molar ion flux [mol/m <sup>2</sup> -s]   |

| $R_f^\pm$                                     | Solid-electrolyte interphase film resistance [Ω-m <sup>2</sup> ]                     |
| $R_s^\pm$                                     | Particle radius in solid phase [m]   |
| $L^j$   | Length of region $j \in \{-, \text{sep}, +\}$  |
| Observer analysis / design parameters         |  |
| $n_{Li,s}, n_{Li,e}$                          | Total moles of lithium in solid, electrolyte phase [mol]                             |
| $\lambda$                                     | Cathode estimation error system parameter  |
| $p^\pm(r), p_0^\pm$                           | Cathode / anode observer gains   |
| $\hat{c}_{ss}^\pm$                            | Estimated cathode surface concentration [mol/m <sup>3</sup> ]                        |
| $\hat{c}_{ss}^\pm$                            | Processed cathode surface concentration [mol/m <sup>3</sup> ]                        |
| $\gamma$                                      | Output inversion gain  |

of  $n_{Li,e}$ . Moreover, the voltage estimation error remains small in Fig. 11(e), 7.5-mV rms. However, there is clear bias in the electrolyte concentration estimate. Fig. 11(b) shows the electrolyte concentrations at the current collectors,  $c_e^\pm(0^\pm, t)$  and the estimation error  $c_e^\pm(0^\pm, t) - \hat{c}_e^\pm(0^\pm, t)$  is shown in Fig. 11(d). The rms errors for the anode and cathode are 7.1% and 6.6%, respectively. These results can be explained by: 1) the electrolyte dynamics are decoupled from the solid-phase dynamics (see Fig. 2) and 2) the voltage output depends on the difference  $\ln c_e(0^+, t) - \ln c_e(0^-, t)$  [see (32)]. That is, the absolute values of  $c_e^\pm(0^\pm, t)$  can be incorrect, provided that the difference between their natural logarithms is correct.

Here, we have examined robustness to parametric uncertainty in  $n_{Li,s}$  and  $n_{Li,e}$ . It is also important to consider robustness to other uncertain parameters, such as diffusivities and conductivities. Comprehensively addressing this issue is an open research topic. Some initial efforts have been made. A sensitivity-based interval observer approach has been recently proposed in [48]. Electrochemical model parameter sensitivity is also examined in [33] and [34] via Fisher information.

## VI. CONCLUSION

This paper derives a reduced electrochemical battery model called the SPMe. The proposed model is most similar to those developed in [18], [20], and [22], yet we analyze the dynamical properties that enable a provably convergent observer design. The SPMe is compared against the DFN model [2], [3] and SPM without electrolyte. We then examine the model's mathematical properties, including stability, lithium conservation, and output function invertibility. Based on several critical features of the SPMe mathematical structure (i.e., subsystem decoupling, marginal stability, conservation of lithium, and local output invertibility), we propose a state estimation scheme summarized in Table II and prove the convergence for the observer and output inversion algorithms. The proposed SPMe observer is characterized by only two tuning parameters—thereby making calibration significantly simpler than KF-based estimators. Finally, we examine the performance attributes and limitations of the SPMe observer using data generated from a DFN model. Simulations demonstrate the convergent estimates on high *C*-rate cycles and transient electric vehicle charge/discharge cycles. State estimation biases occur in the solid or electrolyte phase if the incorrect moles of lithium in the respective subsystem are assumed. This may be acceptable, depending on what states the battery control engineer wishes to accurately monitor (i.e., bulk SOC, surface concentrations, or electrolyte concentrations). Nevertheless, the bias motivates the parameter identification algorithms to estimate the moles of cyclable lithium in each phase—a topic for further investigation. In addition, the proposed SPMe observer can be extended to include temperature dynamics [21] and multimaterial cathodes [29]—topics for further study.

**Scott J. Moura** (S'09–M'13) received the B.S. degree from the University of California at Berkeley, Berkeley, CA, USA, in 2006, and the M.S. and Ph.D. degrees from the University of Michigan, Ann Arbor, MI, USA, in 2008 and 2011, respectively, all in mechanical engineering.

He was a Post-Doctoral Scholar with the Cymer Center for Control Systems and Dynamics, University of California at San Diego, San Diego, CA, USA, and a Visiting Researcher with the Centre Automatique et Systèmes, MINES ParisTech, Paris,

France. He is currently an Assistant Professor and the Director of eCAL in Civil and Environmental Engineering with the University of California at Berkeley. His current research interests include control and estimation theory for PDEs, optimization, machine learning, batteries, electric vehicles, and the smart grid.

Dr. Moura is a recipient of the O. Hugo Schuck Best Paper Award, the Hellman Faculty Fellows Award, the UC Presidential Postdoctoral Fellowship, and the National Science Foundation Graduate Research Fellowship. He has received multiple conference best paper awards as an Advisor and a Student.

**Federico Bribiesca Argomedo** was born in Zamora, Mexico, in 1987. He received the B.Sc. degree in mechatronics engineering from the Tecnológico de Monterrey, Monterrey, Mexico, in 2009, the M.Sc. degree in control systems from Grenoble INP, Grenoble, France, in 2009, and the Ph.D. degree in control systems from the GIPSA-Laboratory, Grenoble University, Grenoble.

He held a post-doctoral position with the Department of Mechanical and Aerospace Engineering, University of California at San Diego, San Diego, CA, USA. He is currently an Assistant Professor with the Department of Mechanical Engineering and Design, Institut national des sciences appliquées de Lyon, Lyon, France, attached to Ampère Laboratory. In particular, he has applied his research techniques to tokamak safety factor control and batteries. His current research interests include control of partial differential equations and nonlinear control theory.

**Reinhardt Klein** received the Dipl.-Ing. degree in cybernetics engineering from the University of Stuttgart, Stuttgart, Germany, in 2009. He is currently pursuing the Ph.D. degree with Otto von Guericke University, Magdeburg, Germany.

He is currently with the Research and Technology Center, Robert Bosch LLC, Palo Alto, CA, USA. His current research interests include modeling, estimation, and control of energy conversion systems, with a particular focus on electrochemical systems.

**Anahita Mirtabatabaei** received the B.S. degree from the Sharif University of Technology, Tehran, Iran, in 2006, and the master's and Ph.D. degrees from the Department of Mechanical Engineering, University of California at Santa Barbara, Santa Barbara, CA, USA, in 2012 and 2013, respectively.

She has been a Research Engineer with Robert Bosch LLC, Palo Alto, CA, USA, since 2013, where she has been involved in state and parameter estimation in advanced battery management systems.

Her current research interests include modeling, estimation, and dynamical behavior analysis of real complex systems.

**Miroslav Krstic** (F'01) holds the Alspach Endowed Chair and is the Founding Director of the Cymer Center for Control Systems and Dynamics with the University of California at San Diego (UCSD), San Diego, CA, USA. He also serves as an Associate Vice Chancellor for Research at UCSD. He has co-authored ten books on adaptive, nonlinear, and stochastic control, extremum seeking, and PDE control covering turbulent flows and delay systems.

Mr. Krstic is a fellow of IFAC, ASME, and IET (U.K.), and a Distinguished Visiting Fellow of the Royal Academy of Engineering. He received the University of California at Santa Barbara Best Dissertation Award and student best paper awards at CDC and ACC. He has received the PECASE, NSF CAREER, and ONR Young Investigator awards, the Axelby and Schuck paper prizes, and the UCSD Research Award. He serves as a Senior Editor of the IEEE TRANSACTIONS ON AUTOMATIC CONTROL and *Automatica*, and has served as the Vice President for Technical Activities and a Fellow Committee Chair of the IEEE.
